

MONITORING OF THE SHELLFISH-KILLING
DINOFLAGELLATE
HETEROCAPSA CIRCULARISQUAMA IN JAPANESE
COASTAL SEA BY INDIRECT FLUORESCENT ANTIBODY
TECHNIQUE

Ichiro Imai, Tomotaka Shiraishi (Kyoto Univ.),
Kiyohito Nagai, Shingo Hiroishi, Shigeru Itakura, Yasunori
Watanabe, Akira Ishikawa and Yasuwo Fukuyo

What is *Heterocapsa circularisquama* ?

Class DINOPHYCEAE

Order Peridiniales

Family Peridineaceae

- Its red tides cause mass mortalities of bivalves.
- This species grows well at high temperatures (optimum 30°C) .
- No growth at 10°C or below.
- Temporary cyst formation under bad conditions.

Mass mortality of short-necked-clam in an intertidal flat

Institute of Fisheries and Environment of Inland
Sea ,Fisheries Research Agency

Problem

The population dynamics has not yet
been clarified
(difficulty in monitoring)

Reason

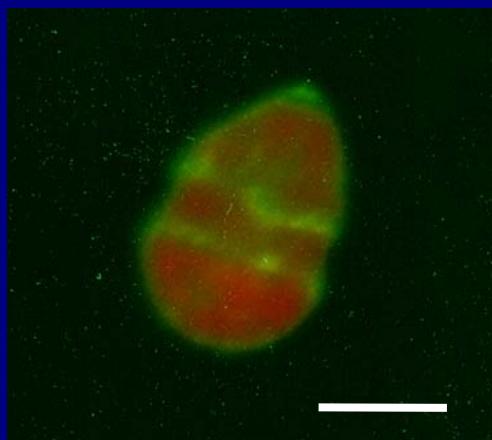

- Small size (ca. $20 \mu\text{m}$ length)
- Presence of morphologically similar species

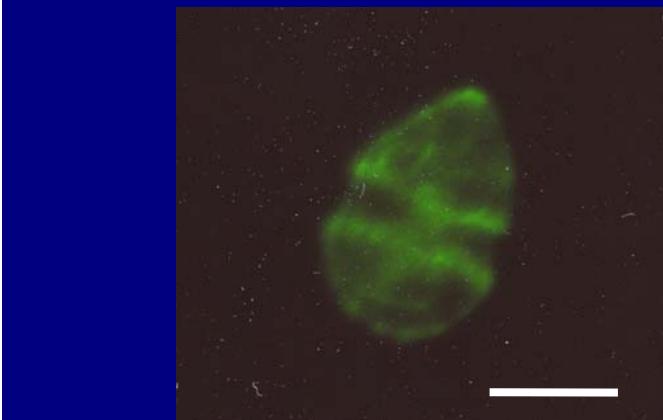

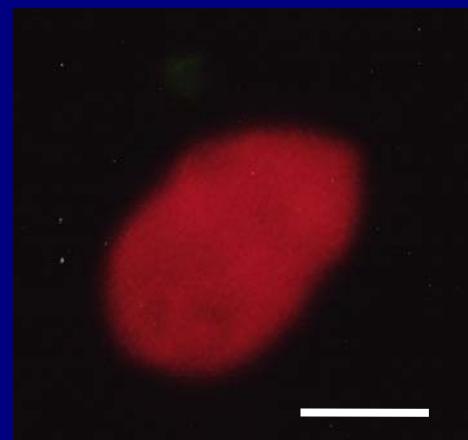

Monitoring by the indirect fluorescent antibody technique using monoclonal antibody

Monitoring of the population dynamics throughout the year in Ago Bay, the red tide area, Mie Prefecture, Japan.

Epifluorescence photomicrographs of *H. circularisquama* and
H. triquetra treated with the indirect fluorescent antibody technique
(Scale Bar, 10 μm)

autofluorescence
Scale Bar, 20 μ m

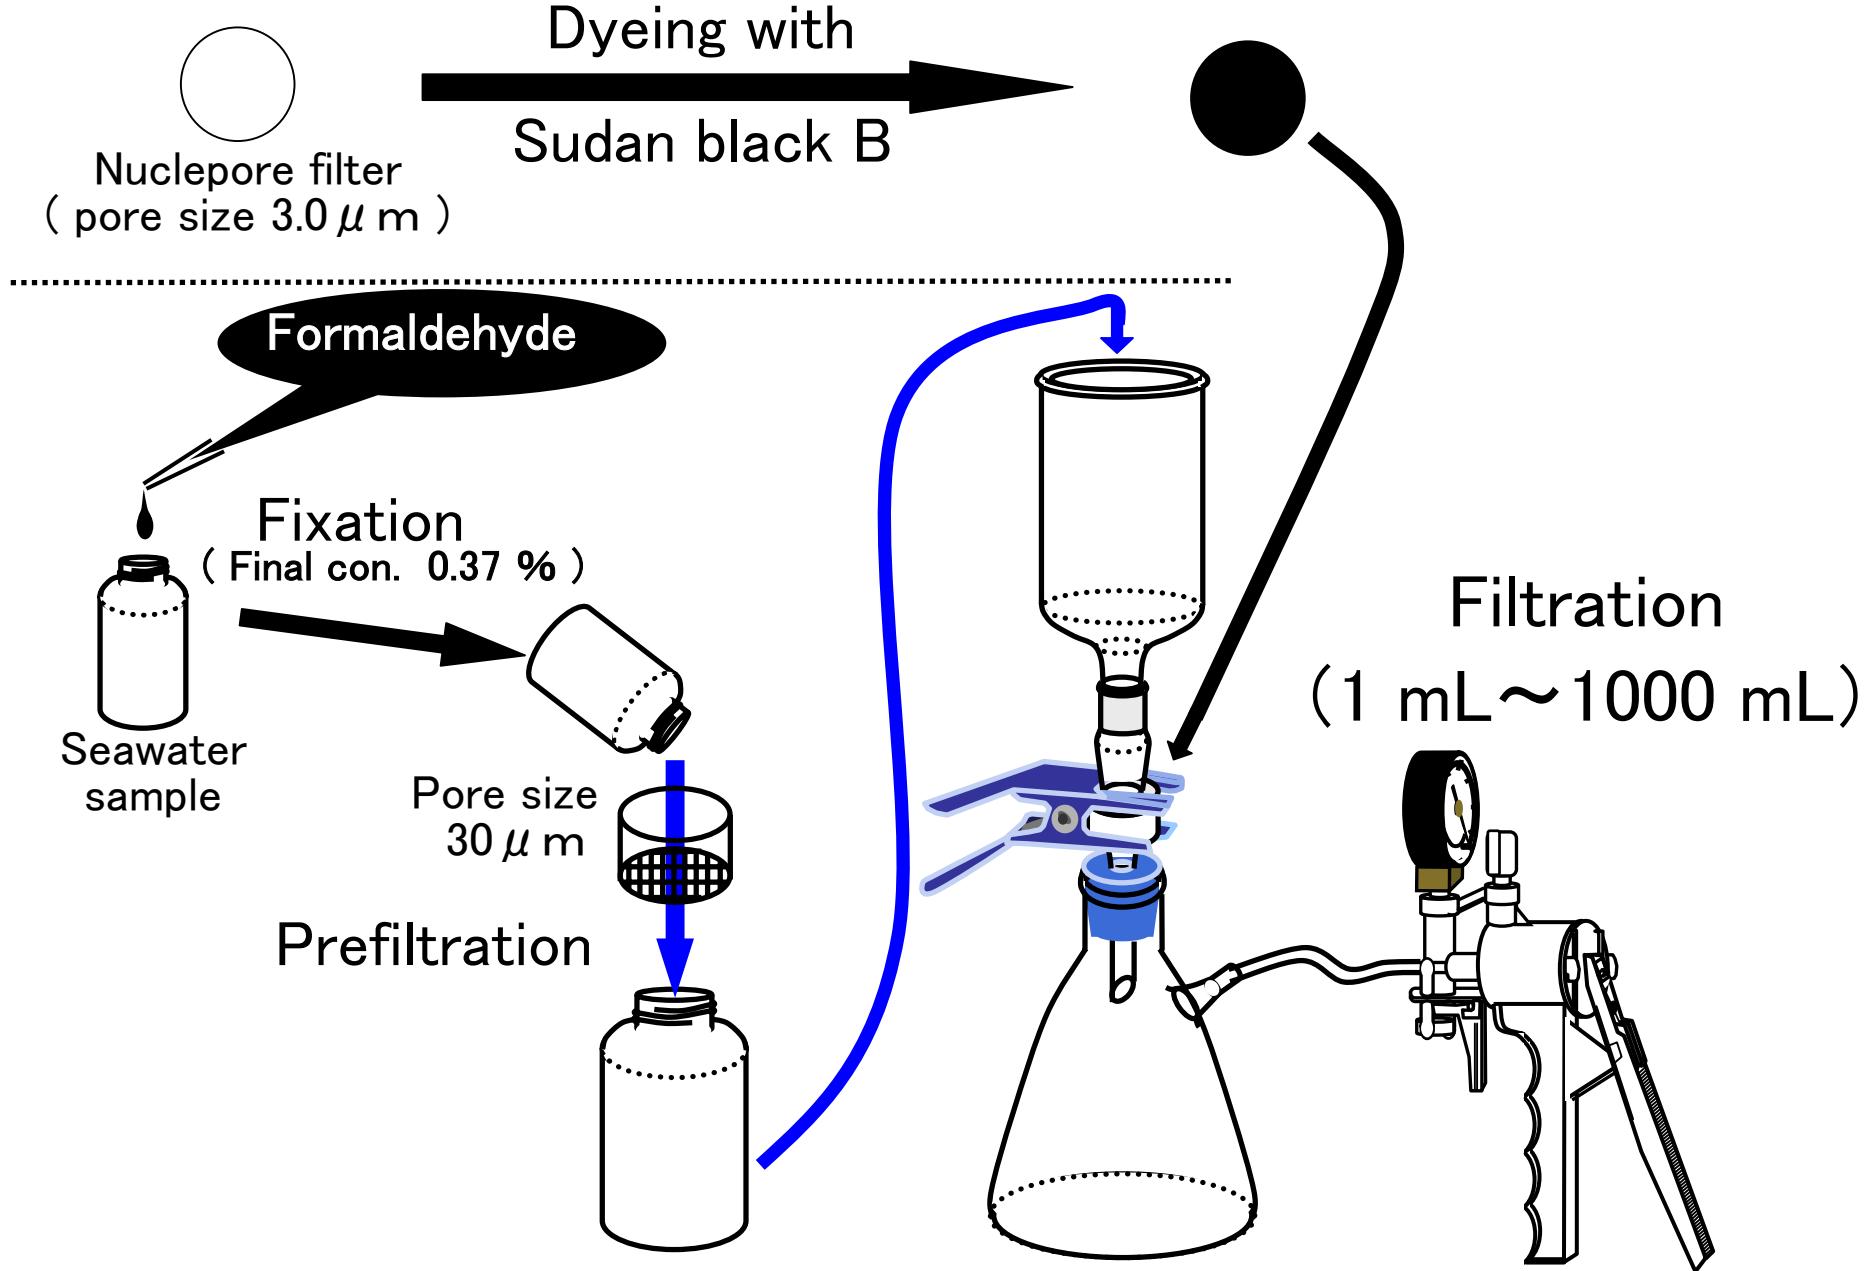

Location of the sampling stations

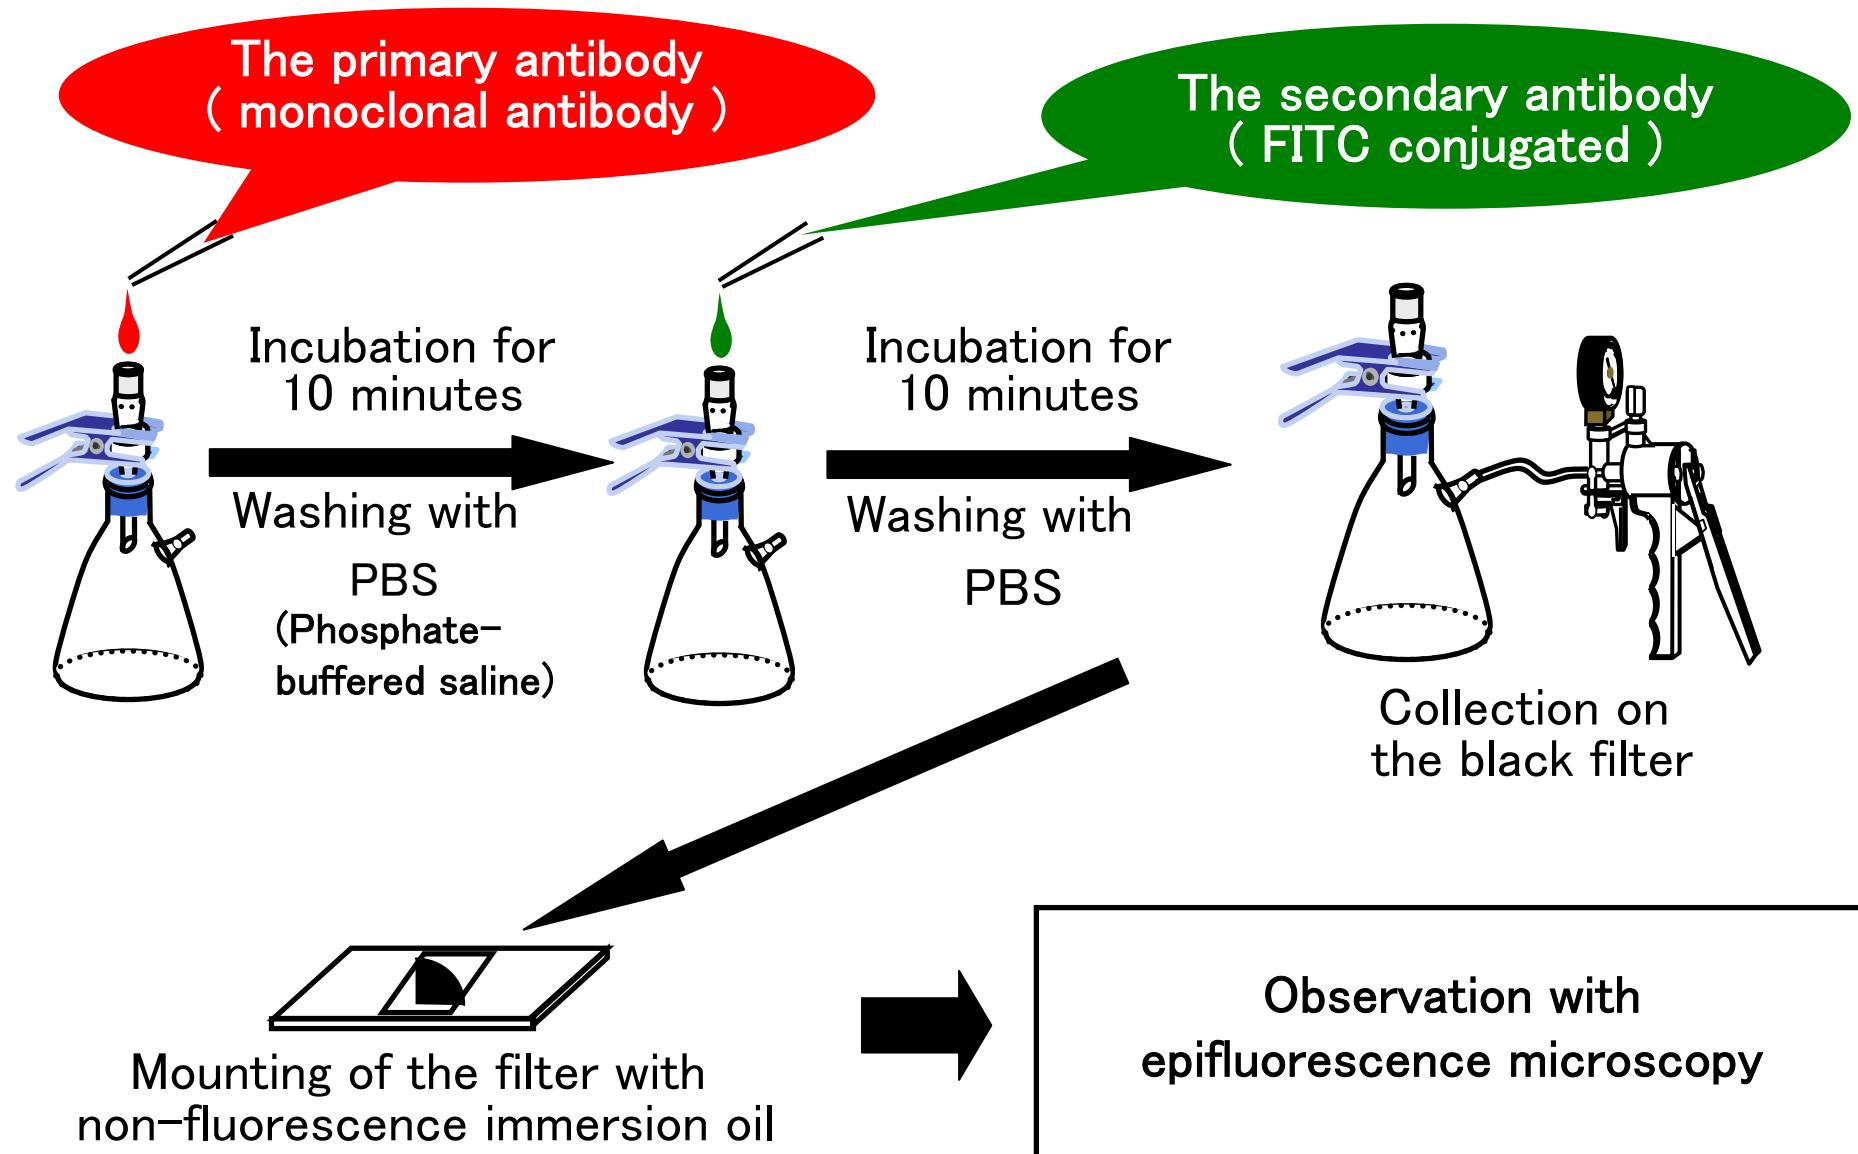

Sampling period: April 2001 ~ March 2003

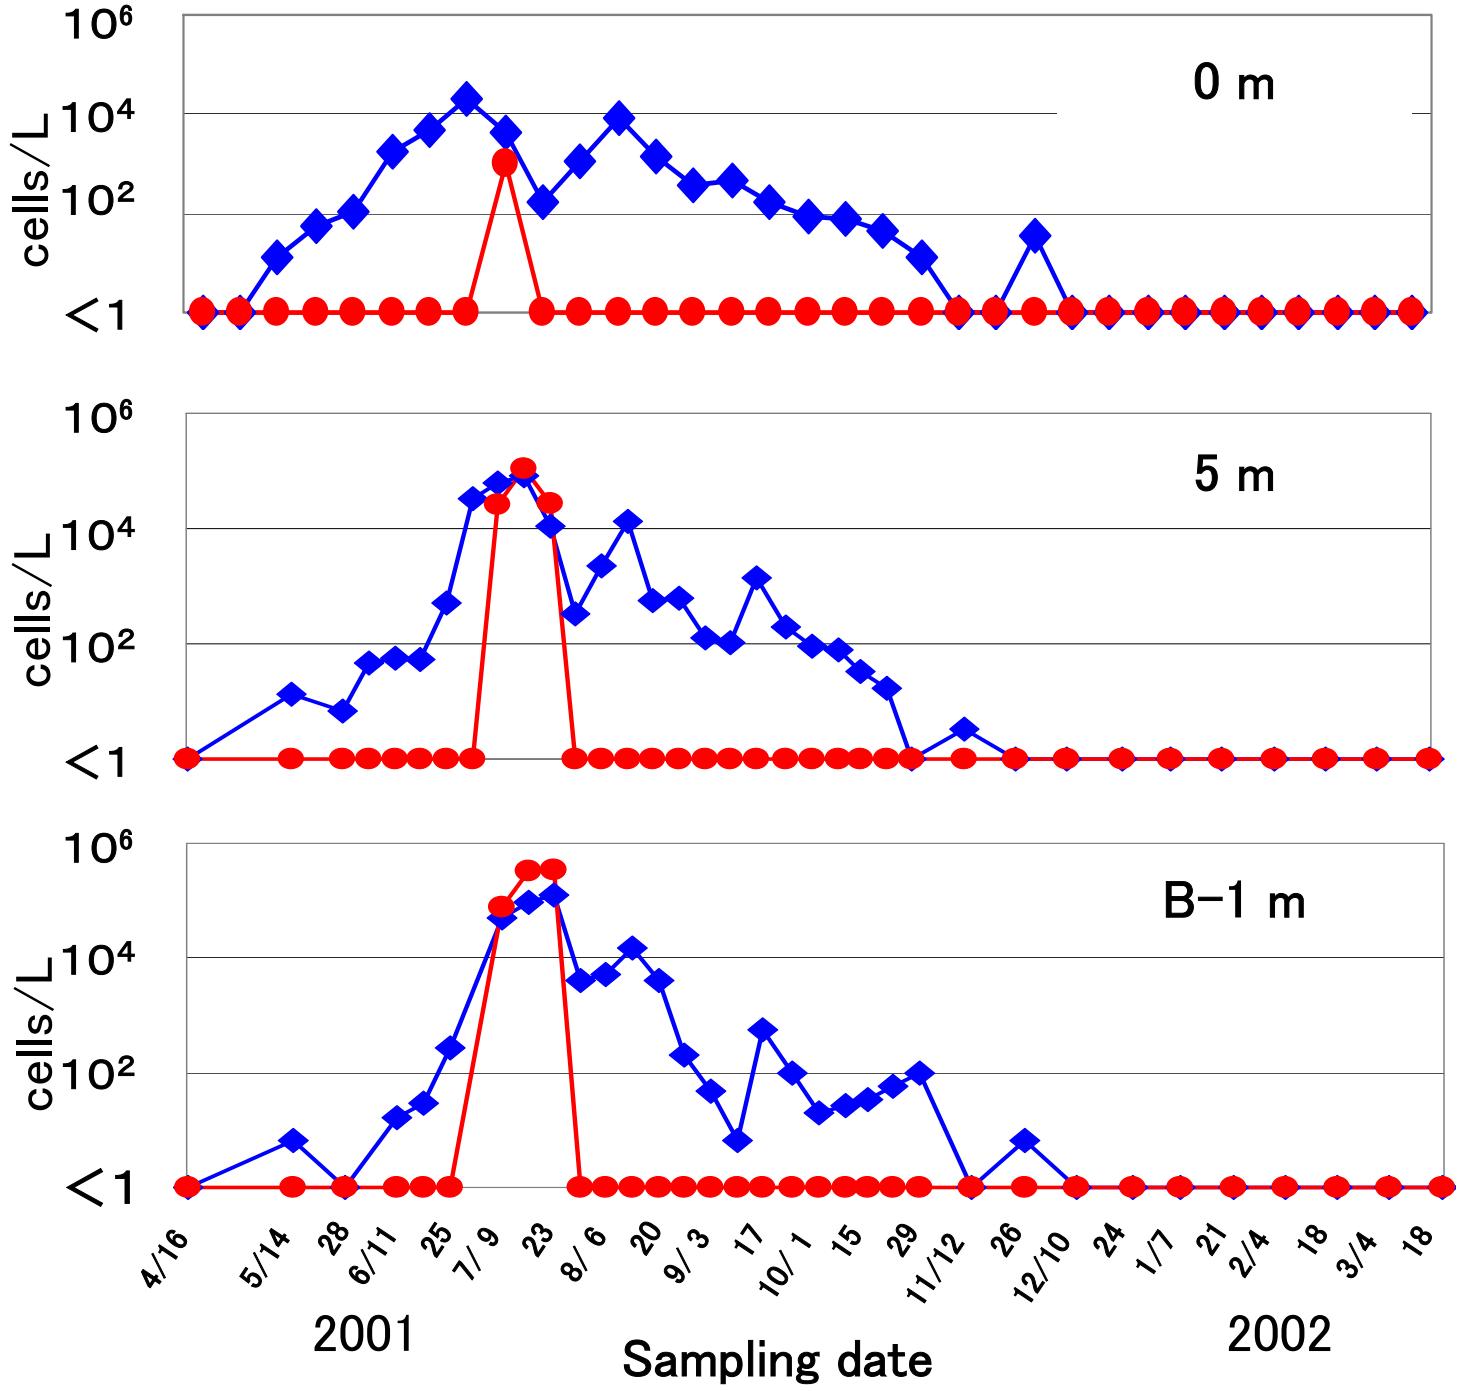

Once a week (in summer and
twice a month in other seasons)

Pretreatment of seawater sample

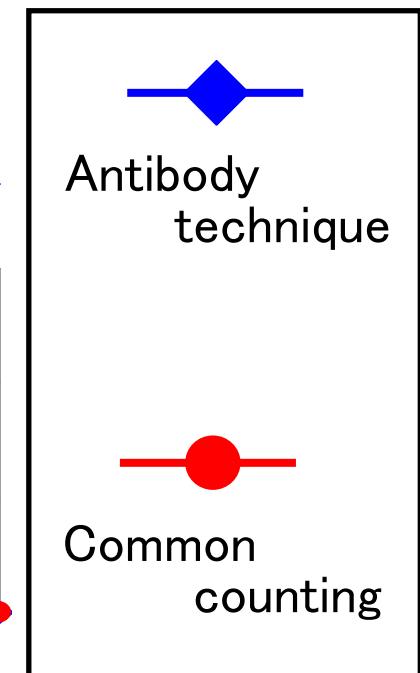

Indirect fluorescent antibody technique

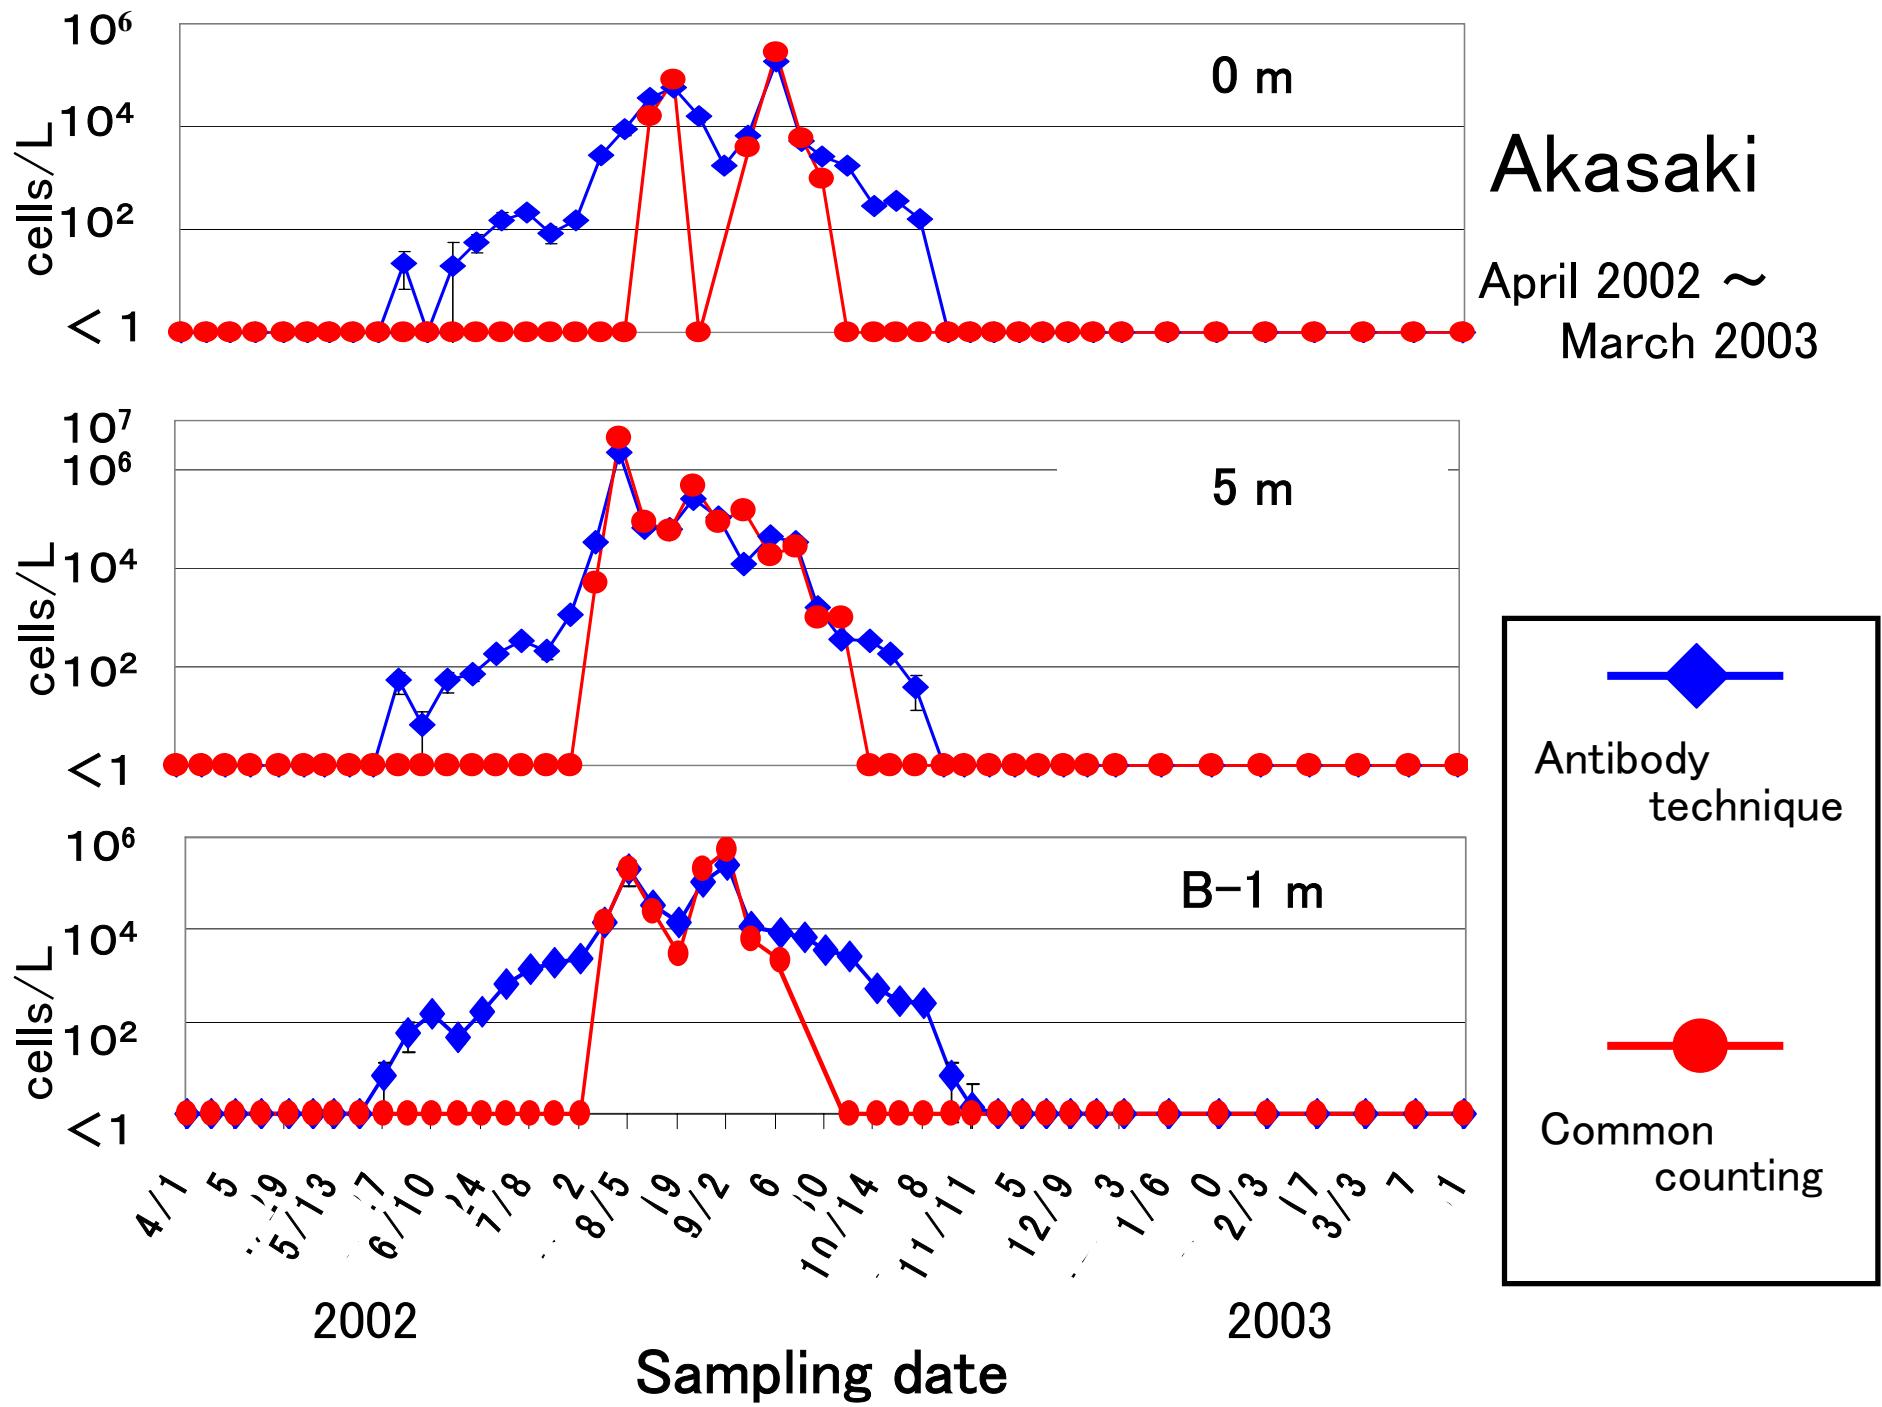

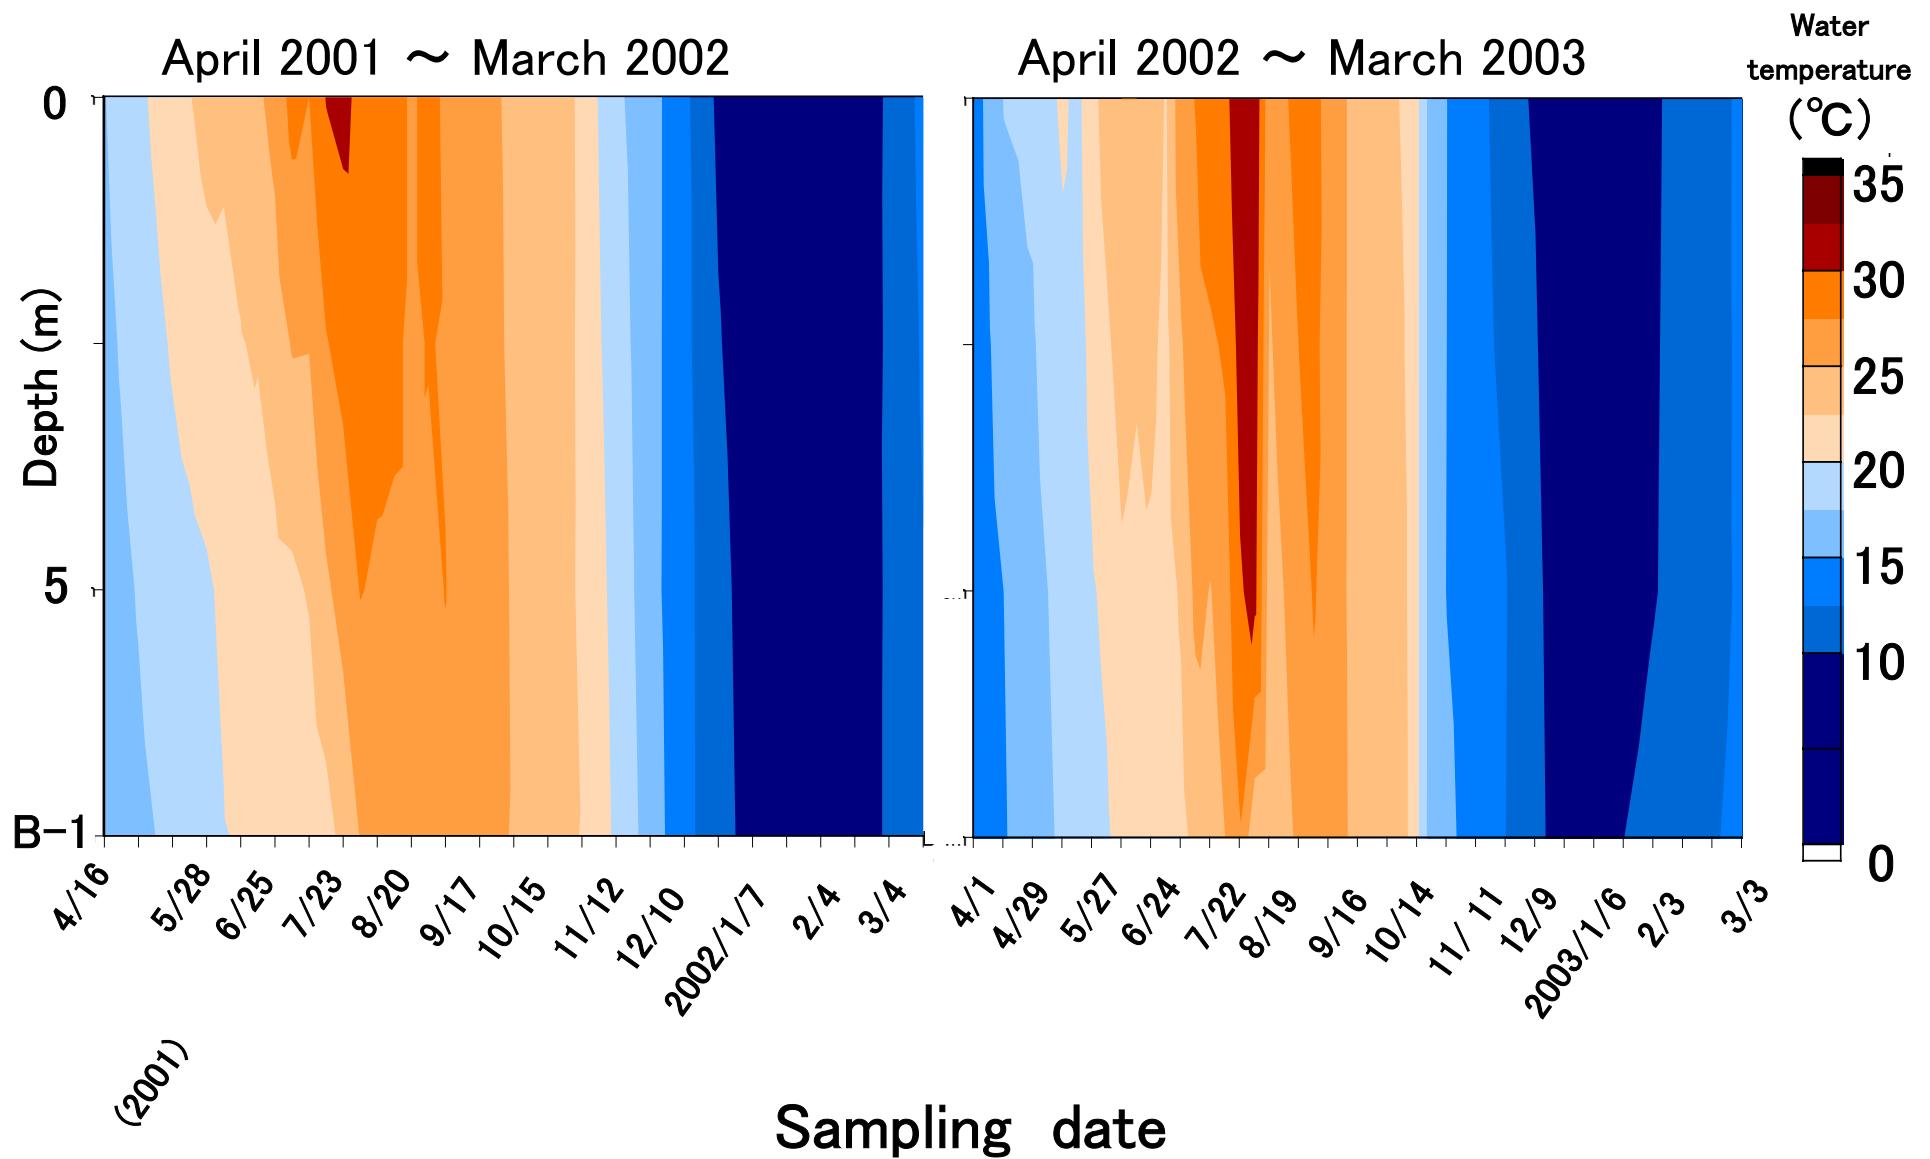

Akasaki

April 2001 ~
March 2002

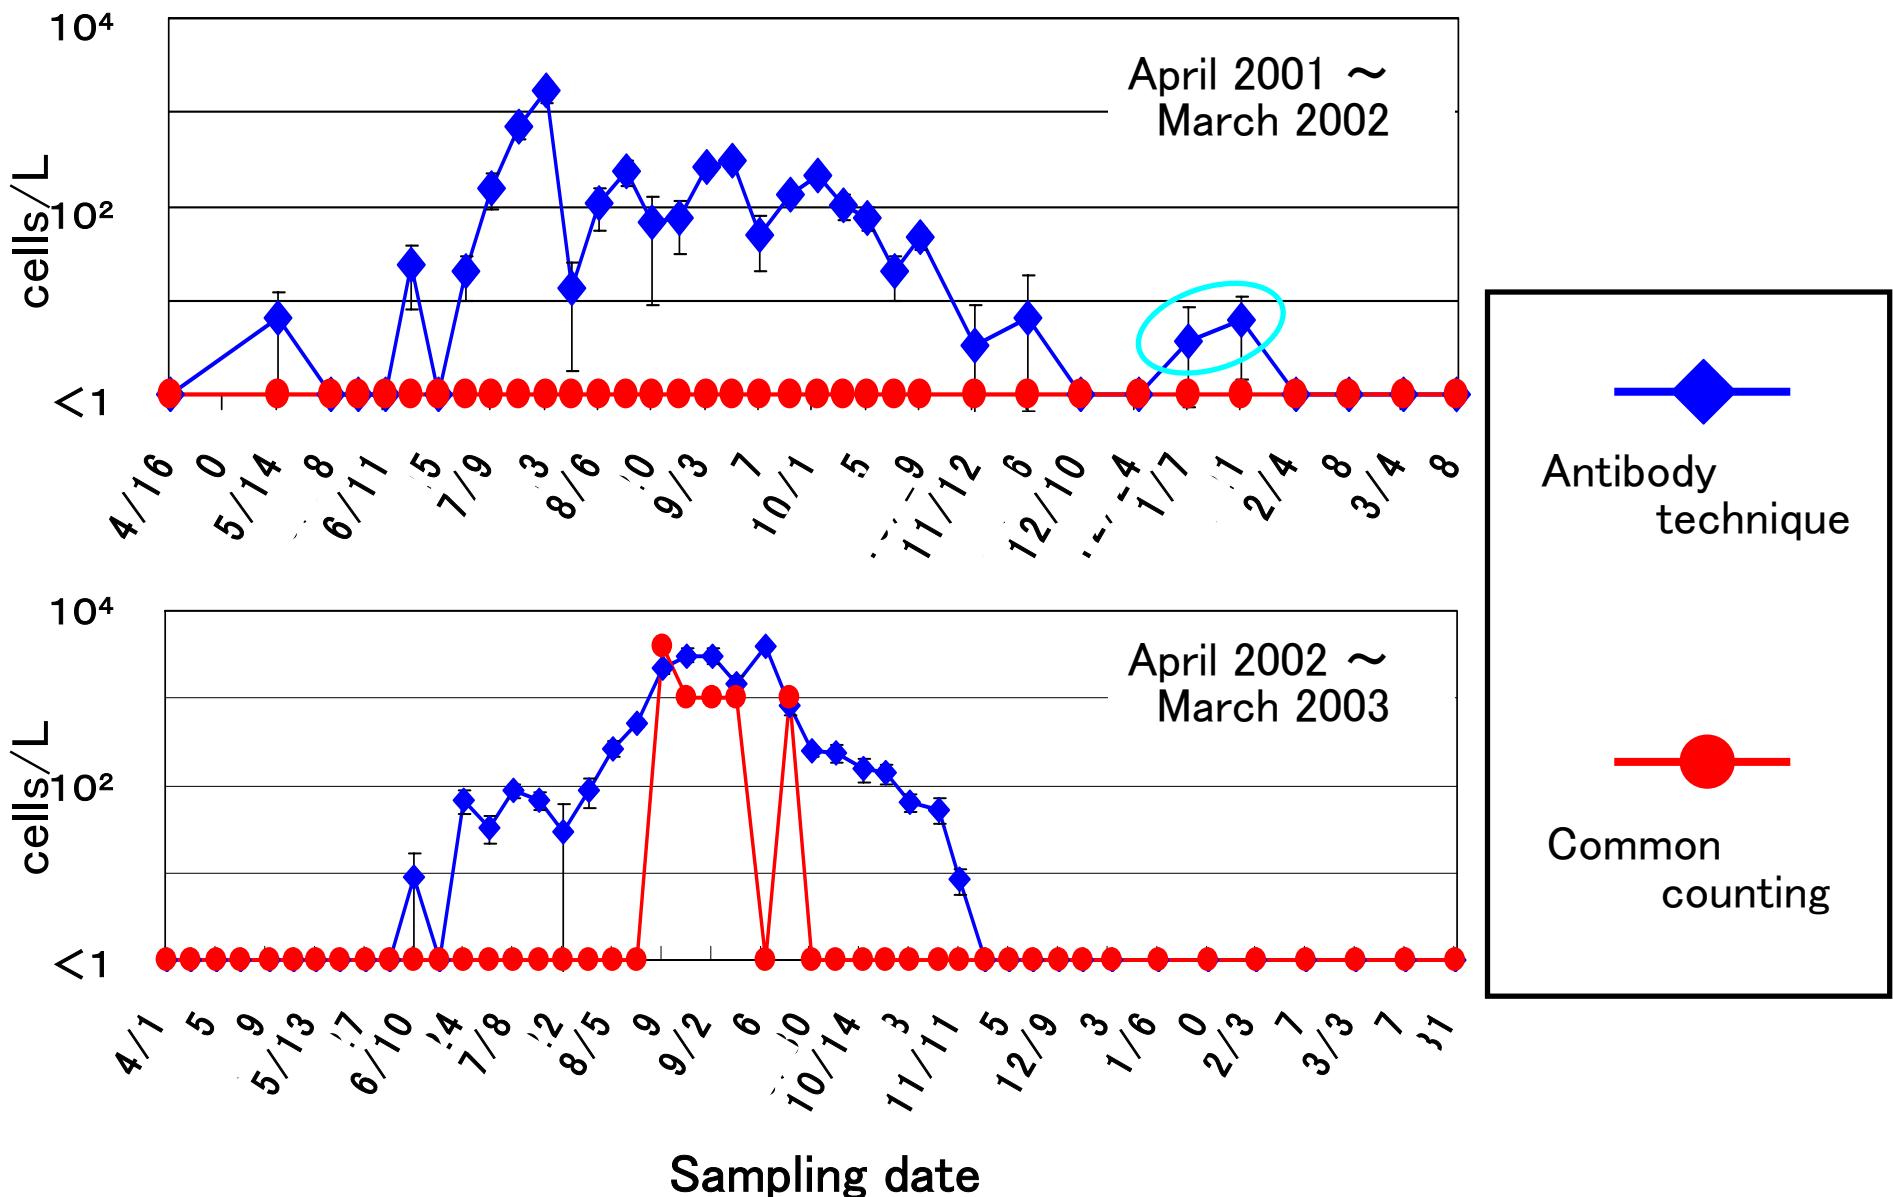

Seasonal changes of water temperature at Akasaki station in Ago Bay

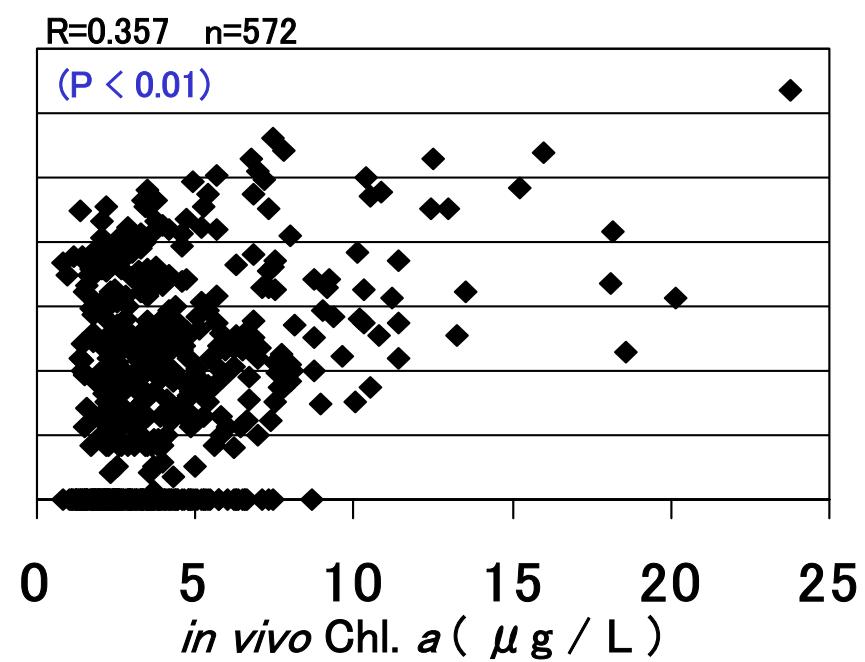

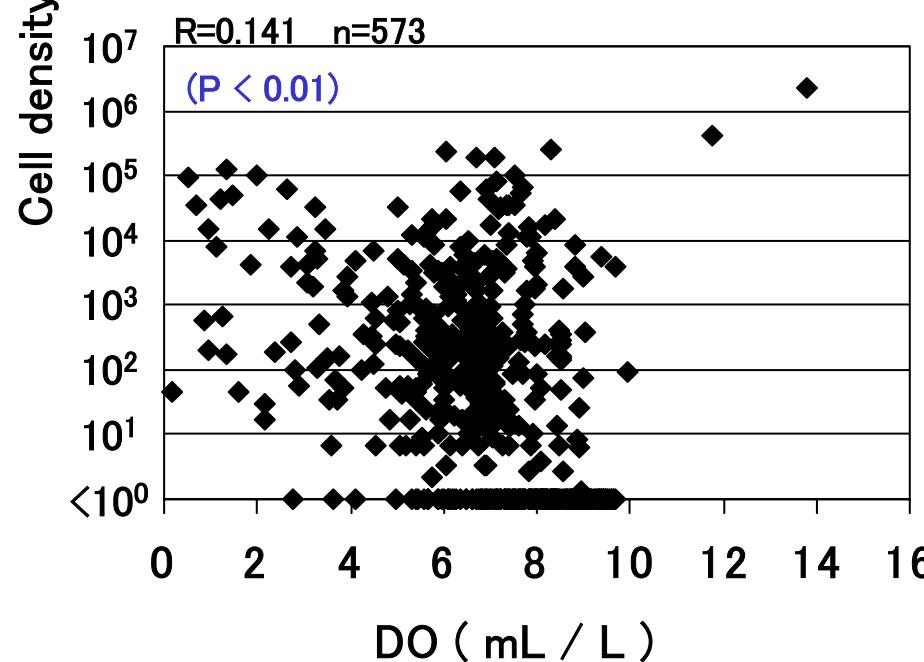

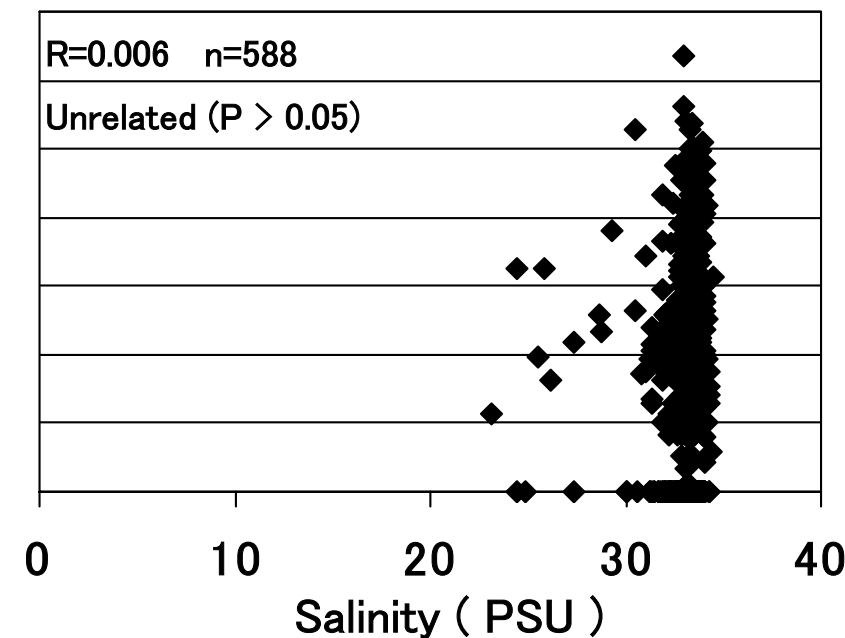

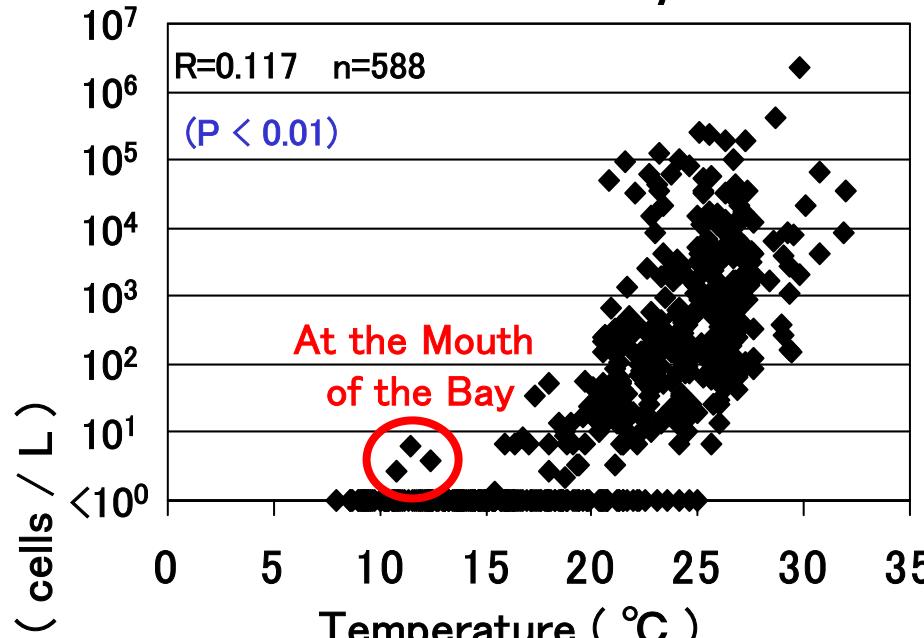

Takonobori 5 m (Mouth of Ago Bay)

Characteristics of population dynamics of *H. circularisquama* in Ago Bay

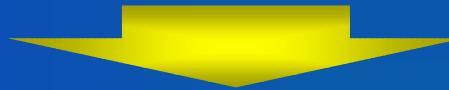

- *H. circularisquama* cells were detected from July to October by the common microscopic counting.
- *H. circularisquama* cells were detected from May to November and in January by the indirect fluorescent antibody technique.
- The cell densities of *H. circularisquama* were high in summer.
- Decline of the cell density of *H. circularisquama* delayed at the mouth of Ago Bay, and the cells were detected even in January.

H. circularisquama and environmental factors

Summary

- Common microscopic counting detect *H. circularisquama* only at cell density of 1000 cells / L or higher.
- The present antibody technique can detect *H. circularisquama* at cell density of 10 cells / L or lower.

We could follow the population dynamics of *H. circularisquama* throughout the year by the indirect fluorescent antibody technique.

- *H. circularisquama* always exists at high temperature ($>25^{\circ}\text{C}$) in Ago Bay.

Future study

Overwintering mechanisms are unknown in
Heterocapsa circularisquama.

- Detection of *H. circularisquama* cells in winter season is essential with this method using large volume sea water in Ago Bay.
- Detection of *H. circularisquama* in warmer bays (winter temperature $> 12^{\circ}\text{C}$) in winter.
